

OPEN SOURCE · WHITELABEL **COMING SOON**

The self-learning context layer for funds.

The highly versatile context layer for professional fund controlling. Built for demanding agentic loops.

The prompting era is over.

- One question about a management fee touches the partnership agreement, three amendments, two side letters and eighteen account sheets.
- Context windows grew — and the problem grew with them. Cost rises linearly, accuracy falls.
- Context rot: read a million tokens and you remember the beginning and the end, and lose the middle.
- The middle is where the superseded version sits.

┃ A better prompt does not fix that. A loop does — given somewhere the data already lies in order.

The model is handed the data itself, not the data inside its context.

- Query the ontology, call the reranker, read the hits, fold the rest away — and start again until the answer holds.
- Recursive means the model starts fresh copies of itself to read what it does not want in its own head.
- What comes back is not the pages but the result.
- Its working context stays flat — so the loop keeps going long after a single-prompt system has filled up.

Same work, same question — and a context that stays flat.

Four shapes — told apart by what gets handed over.

Turn-based

HANDED OVER

the check

TRIGGERED BY

a task someone sets

ENDS

when the agent judges the work done

SUITED TO

short, open-ended tasks with someone reading along

Goal-based

HANDED OVER

the stop condition

TRIGGERED BY

the previous pass finishing

ENDS

when an independent check confirms the goal —
or the pass limit bites

SUITED TO

tasks with a verifiable “done”

Time-based

HANDED OVER

the trigger

TRIGGERED BY

an interval

ENDS

when cancelled, or when the watched work
finishes

SUITED TO

recurring work, waiting on external state

Proactive

HANDED OVER

the task itself

TRIGGERED BY

an event or a schedule

ENDS

when operations switch it off

SUITED TO

standing streams: inbox, reconciliation,
migration

Loop management asks: what does it check itself against? what stops it? what does it draw on? The first question is the hard one.

A loop may only run alone if it can check its own result.

- The booking has two legs, and they close.
- The amount appears in a document — with a page and a paragraph.
- The version it came from is the one that holds today.
- The occurrence is complete: no capital call without its counter-booking, no valuation without a period.

An ontology can answer that; a pile of documents cannot. The context layer is not just the data source — it is the verifier.

One layer beneath every function.

No function gets its own filing cabinet. They all reach for the same data, the same citations, the same validity.

A ledger, not a pile of chunks.

An amount without a subject, a counterparty or a date is not information. Five kinds of sentence: legal_entity, entity_group, event, transaction, measurement — and the citation underneath all of them.

A reranker that speaks the language of the house.

- First stage for recall: BM25, trigram, vector search. Broad — but understanding nothing of the question.
- Second stage decides: a cross-encoder reads question and passage together, one calibrated score.
- Off-the-shelf models fail on German financial language — and cannot see that the 2021 version is superseded.
- So one is trained on the holdings: pairs from the ontology, hard negatives from superseded versions.
- Single-digit milliseconds — reranking on every typed word.

Every pass makes the retrieval sharper.

The loop queries the retrieval, the retrieval improves from the loop, the better loop produces cleaner signal. A framework of data, loops and retrieval mechanics — grown in one place.

Eight areas. The same documents. Kept separately eight times.

The partnership agreement decides the fee calculation, the tax treatment, the distribution waterfall and what an LP is shown. A capital call is a booking, an audit exhibit, a capital-account line and a portal document at once. Today both exist several times over — in-house, at the administrator, at the tax advisor, at the law firm, in the data room.

Market research & sourcing

It starts with a thesis, not a deal.

- Thesis development and trend research
- Outbound across market databases, registers, trade media
- Inbound: decks from inbox, messenger, form
- Network, events, scout programmes

INVOLVED

investment team

market data providers

company registers

IN THE SYSTEM

Entities fall out of every deck — company, founders, round, valuation — each with its citation beside it. That the same company is knocking for the third time is recognised by content, not by filename.

CRM & pipeline management

The real capital of a fund is its relationships.

- Deal-flow tracking across stages
- Founders, co-investors, LPs, advisors
- Tasks and workflows through the deal process
- Reporting on pipeline conversion

INVOLVED

investment team

CRM system

IN THE SYSTEM

The CRM stays where it is — the layer feeds it. Who appears in the deck, who is on the register, who signed the mail: that becomes contacts and links without anyone retyping them.

Due diligence

Five fields, one close at which everything has to agree.

- Commercial, tech, team, legal, financial DD
- Sequence through to confirmatory legal sign-off
- Data room review and cap table analysis
- Reference calls and market validation

INVOLVED

investment team

external legal and tax advisors

data room provider

IN THE SYSTEM

One loop per stage with its own stop condition: it stops when every statement needing evidence either has a citation or is marked open. The reconciliation at the end is a query, not a judgement.

Investment execution & closing

This produces the most expensive record in the whole fund.

- Term sheet, SPA and SHA negotiation
- Confirmatory legal DD
- Signing and funds flow
- Cap table entry and holding documentation

INVOLVED

investment team

external law firm

bank

IN THE SYSTEM

The system creates it itself: the holding as a two-legged booking, the occurrence as an event, the company as an entity, the agreement as the citation — and proposes the filing. Confirmation is manual.

Portfolio management & value creation

The work that runs for years.

- KPI monitoring across holdings
- Request process, data source per holding
- Centralisation and plan versus actual
- Board seats, hiring, BD, follow-on rounds

INVOLVED

investment team

portfolio companies

IN THE SYSTEM

Every reported figure becomes a measurement with period, scenario and citation. Plan versus actual is then not a maintained spreadsheet but two scenarios of the same measurement. The request itself runs as a time-based loop.

Finance & fund operations

The core — and the only area that starts again every quarter.

- Fund accounting, NAV, capital accounts, annual accounts
- Capital calls, distributions, reporting, account statements
- Waterfall, hurdle, clawback incl. interest and fees
- Regulatory, tax, treasury, governance, audit, valuation

IN THE SYSTEM

A capital call is not a PDF but an occurrence with a date, a two-legged booking per investor and a citation with page and paragraph. NAV, waterfall and hurdle compute on the same bookings — not on a copy in a spreadsheet.

INVOLVED

in-house fund finance

fund administration

tax advisors

auditors

banks

Investor relations & fundraising

An LP sees two things: what they signed and what they get.

- LP onboarding, KYC, subscription questionnaire
- Closing support and digital signing
- Fundraising materials and LP communication
- Key account management

IN THE SYSTEM

An LP is an entity with a commitment, drawdown history, capital account, side letters and tax status. If a side letter sets a different fee, that fee holds in the calculation — because it sits in the ledger.

INVOLVED

investor relations

fund administration

KYC provider

Legal & compliance

Agreements are where versions get expensive.

- Fund structuring, LPA, partnership agreements
- Ongoing compliance and registrations
- Contract and service-provider management

INVOLVED

external law firm

compliance

fund administration

IN THE SYSTEM

LPA, amendments, side letters and superseded drafts sit as a linked chain. The reranker is trained on exactly that: the version that holds on top, the history visible behind it.

Whoever holds the context layer holds the answer.

- Models become interchangeable — better, cheaper and more alike every year.
- Not interchangeable: ordered, cited, queryable data.
- Not interchangeable: loops that check themselves against that data and may therefore run alone.
- Not interchangeable: a retrieval that sharpens with every pass.
- The three hold each other up. Something like that is built once — where the documents are.

The ontology takes shape with the documents, not
after them.
